

Division of Microbiology Department of Oral Biology

Outline

We engage in educations on microbiology and immunology regarding with a general medicine and dentistry, and in researches on microbiology.

Faculty members

Professor

Keiji NAGANO, Ph D. (Left)

Lecturer

Hiroshi MIYAKAWA, Ph D. (Center)

Assistant professor

Mari FUJITA, D.D.S., Ph D. (Right)

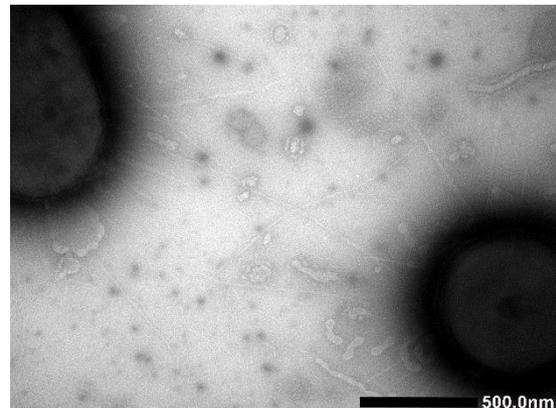

Research Interests

We are interested in the biochemical and molecular genetic analyses of bacterial pathogenic factors. Topics currently pursued include mechanisms of biofilm formation of oral bacteria, especially periodontopathic bacteria such as *Porphyromonas gingivalis*, *Tannerella forsythia*, *Treponema denticola* and *Prevotella* spp. We are also interested in the exploitation of antimicrobial regents.

Current Projects

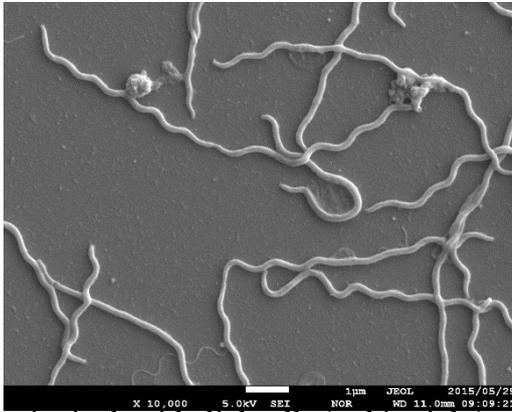

- Functional and structural analyses of fimbriae in *Porphyromonas gingivalis***
P. gingivalis expresses thin filamentous structures, fimbriae, on the surface (see right). They adhere to the gingival tissues and form a biofilm largely through the fimbriae.

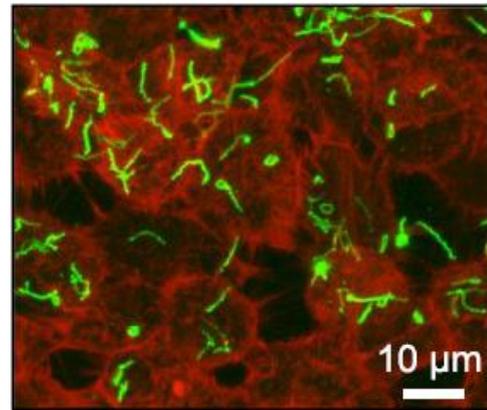

(2) **Analysis of biofilm formation in *Treponema denticola***

Oral spirochete *T. denticola* colonizes on gingival tissues with multi-species biofilm. However, the mechanisms of adherence to the gingiva and biofilm formation are not elucidated.

T. denticola is an oral spirochete (left, and green in right), and adheres to the

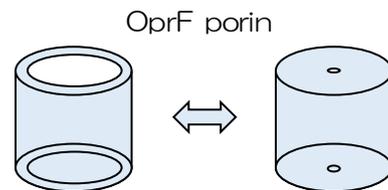

gingival epithelial cells (red in right).

(3) **Analysis of conformational change of OprF porin in *Pseudomonas aeruginosa***

P. aeruginosa shows a highly intrinsic resistance to antibiotics largely due to the low outer membrane permeability. The low permeability is caused by the folding of the major porin OprF; a majority (~95%) forms a closed-channel conformer.

Open conformer
5%

Closed conformer
95%
